Introduction

This document provides information on the most frequently asked questions (FAQ) about the Cisco wireless LAN controller (WLC).

Refer to Cisco Technical Tips Conventions for more information on document conventions.

General FAQ

Q. What is a wireless LAN controller (WLC)?

A. Wireless networks have become a necessity today. Many corporate environments require deployment of wireless networks on a large scale. Cisco has come up with the concept of the Cisco Unified Wireless Network (CUWN) solution, which helps make it easier to manage such large scale deployments. WLC is a device that assumes a central role in the CUWN. Traditional roles of access points, such as association or authentication of wireless clients, are done by the WLC. Access points, called Lightweight Access Points (LAPs) in the unified environment, register themselves with a WLC and tunnel all the management and data packets to the WLCs, which then switch the packets between wireless clients and the wired portion of the network. All the configurations are done on the WLC. LAPs download the entire configuration from WLCs and act as a wireless interface to the clients. For more information on how a LAP registers with a WLC, refer to the document Lightweight AP (LAP) Registration to a Wireless LAN Controller.

Q. What is CAPWAP?

A. In controller software release 5.2 or later, Cisco lightweight access points use the IETF standard Control and Provisioning of Wireless Access Points protocol (CAPWAP) in order to communicate between the controller and other lightweight access points on the network. Controller software releases prior to 5.2 use the Lightweight Access Point Protocol (LWAPP) for these communications.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a controller to manage a collection of wireless access points. CAPWAP is being implemented in controller software release 5.2 for these reasons:

- ◆ To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP

- ◆ To manage RFID readers and similar devices
- ◆ To enable controllers to interoperate with third-party access points in the future

LWAPP-enabled access points can discover and join a CAPWAP controller, and conversion to a CAPWAP controller is seamless. For example, the controller discovery process and the firmware downloading process when you use CAPWAP are the same as when you use LWAPP. The one exception is for Layer 2 deployments, which are not supported by CAPWAP.

You can deploy CAPWAP controllers and LWAPP controllers on the same network. The CAPWAP-enabled software allows access points to join either a controller that runs CAPWAP or LWAPP. The only exception is the Cisco Aironet 1140 Series Access Point, which supports only CAPWAP and therefore joins only controllers that run CAPWAP. For example, an 1130 series access point can join a controller that runs either CAPWAP or LWAPP whereas an 1140 series access point can join only a controller that runs CAPWAP.

For more information, refer to the Access Point Communication Protocols section of the configuration guide.

Q. Are there any guidelines for using CAPWAP?

A. Follow these guidelines when you use CAPWAP:

- ◆ If your firewall is currently configured to allow traffic only from access points that use LWAPP, you must change the rules of the firewall to allow traffic from access points that use CAPWAP.
- ◆ Make sure that the CAPWAP UDP ports 5246 and 5247 (similar to the LWAPP UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the controller.
- ◆ If access control lists (ACLs) are in the control path between the controller and its access points, you need to open new protocol ports to prevent access points from being stranded.

The access points use a random UDP source port to reach these destination ports on the controller. In controller software release 5.2, LWAPP was removed and replaced by CAPWAP, but if you have a new out-of-the-box access point, it could try to use LWAPP to contact the controller before it downloads the CAPWAP image from the controller. Once the access point downloads the CAPWAP image from the controller, it uses only CAPWAP to communicate with the controller.

Note: After 60 seconds of trying to join a controller with CAPWAP, the access point falls back to using LWAPP. If it cannot find a controller using LWAPP within 60 seconds, it tries again to join a controller using CAPWAP. The access point repeats this cycle of switching from CAPWAP to LWAPP and back again every 60 seconds until it joins a controller.

An access point with the LWAPP recovery image (an access point converted from autonomous mode or an out-of-the-box access point) uses only LWAPP to try to join a controller before it downloads the CAPWAP image from the controller.

Q. Where can I find more information about the initial configuration of WLCs in my WLAN network?

A. In order to configure the WLC for basic operation, refer to the document Wireless LAN Controller and Lightweight Access Point Basic Configuration Example.

Q. What are the various options available to access the WLC?

A. This is the list of options available to access the WLC:

- ◆ GUI access with HTTP or HTTPS
- ◆ CLI access with Telnet, SSH, or console access
- ◆ Access through service port

For more information on how to enable these modes, refer to the Using the Web–Browser and CLI Interfaces section of the document Cisco Wireless LAN Controller Configuration Guide, Release 5.1. Usually, the management interface IP address is used for GUI and CLI access. Wireless clients can access the WLC only when the option **Enable Controller Management to be accessible from Wireless Clients** is checked. In order to enable this option, click the **Management** menu of the WLC, and click **Mgmt via Wireless** on the left–hand side. WLC can also be accessed with one of its dynamic interface IP addresses. Use the **config network mgmt–via–dynamic–interface** command to enable this feature. Wired computers can have only CLI access with the dynamic interface of the WLC. Wireless clients have both CLI and GUI access with the dynamic interface.

Q. How do I use the USB console port on the Cisco 5500 series Wireless LAN Controller?

A. The USB console port on the 5500 series controllers connects directly to the USB connector of a PC using a USB Type A to 5–pin mini Type B cable.

Note: The 4–pin mini Type B connector is easily confused with the 5–pin mini Type B connector. They are not compatible. Only the 5–pin mini Type B connector can be used.

For operation with Microsoft Windows, the Cisco Windows USB console driver must be installed on any PC connected to the console port. With this driver, you can plug and unplug the USB cable into and from the console port without affecting Windows HyperTerminal operations. Only one console port can be active at a time. When a cable is plugged into the USB console port, the RJ–45 port becomes inactive. Conversely, when the USB cable is removed from the USB port, the RJ–45 port becomes active

For detailed information, refer to Using the Cisco 5500 Series Controller USB Console Port.

Q. How do I access the GUI configuration wizard on a 4400 controller?

A. In order to configure the basic settings on a 4400 controller using the GUI configuration wizard, you must connect to the service port of the controller. Next, configure your PC to use the same subnet as the controller service port; the IP address on service port when configuring the WLC for the first time is 192.168.1.1. Start Internet Explorer 6.0 SP1 (or later) or Firefox 2.0.0.11 (or later) on your PC, and browse to <http://192.168.1.1>. The GUI Configuration wizard appears.

For detailed information on this topic, refer to the Cisco Wireless LAN Controller Configuration Guide, Release 6.0.

Q. How do I access the WLC from a remote location?

A. You can use Telnet and SSH to access WLC from a remote location. Telnet is a protocol used for remote access; SSH is also a protocol used for remote access, but it includes added security. For more information, refer to the Configuring SSH and Telnet Sessions section of

Q. Can I connect different ports of the WLC to different switches?

A. If you plan to implement LAG, you should not connect the wireless LAN controller ports to different switches because LAG bundles all of the controller's distribution system ports into a single 802.3ad port channel (thereby reducing the number of IP addresses needed to configure the ports on your controller). When you enable LAG, you can configure only one AP–manager interface because only one logical port is needed. LAG removes the requirement to support multiple AP–manager interfaces.

Cisco 4400 series controllers support LAG in software release 3.2 and higher, and LAG is enabled automatically on the controllers within the Cisco WiSM and the Catalyst 3750G Integrated wireless LAN controller Switch. With LAG enabled, a 4402 controller's logical port supports up to 50 access points, a 4404 controller's logical port supports up to 100 access points, and the logical port on each Cisco WiSM controller supports up to 150 access points.

Without LAG, each distribution system port on the controller supports up to 48 access points.

If you want to connect controller ports to different switches, LAG must be disabled, and you must configure one (1) AP Manager Interface for each WLC distribution port.

For more information on wireless LAN controller ports and interfaces, refer to Overview of Ports and Interfaces.

For information on configuring LAG on WLCs, refer to Enabling Link Aggregation.

Q. How does a WLC switch packets?

A. All the client (802.11) packets are encapsulated in a LWAPP packet by the LAP and sent to the WLC. WLC decapsulates the LWAPP packet and acts based on the destination IP address in the 802.11 packet. If the destination is one of the wireless clients associated to the WLC, it encapsulates the packet again with the LWAPP and sends it to the LAP of the client, where it is decapsulated and sent to the wireless client. If the destination is on the wired side of the network, it removes the 802.11 header, adds the Ethernet header, and forwards the packet to the connected switch, from where it is sent to the wired client. When a packet comes from the wired side, WLC removes the Ethernet header, adds the 802.11 header, encapsulates it with LWAPP, and sends it to the LAP, where it is decapsulated, and the 802.11 packet is delivered to the wireless client. For more information about this, refer to the LWAPP Fundamentals section of the document Deploying Cisco 440X Series Wireless LAN Controllers.

Q. When should I use the master controller mode on a WLC?

A. When there is a master controller enabled, all newly added access points with no primary, secondary, or tertiary controllers assigned associate with the master controller on the same subnet. This allows the operator to verify the access point configuration and assign primary, secondary, and tertiary controllers to the access point using the **All APs > Details** page.

The master controller is normally used only when adding new access points to the Cisco Wireless LAN solution. When no more access points are being added to the network, Cisco WLAN solution recommends that you disable the master controller.

Q. Does the 4400 WLC route packets between VLANs?

A. The 4400 WLC is an appliance that attaches to your network but does not function like a router. There must be a Layer 3 device to route packets between VLANs. The WLC maps the SSID of the clients to the VLAN subnet and puts them back out on the management interface for the upstream routers to route packets.

Q. How do I configure WLAN on a WLC?

A. WLAN is similar to that of SSID in the access points. It is required for a client to associate with its wireless network. In order to configure a WLAN on a WLC, refer to the sample configuration in the document Guest WLAN and Internal WLAN using WLCs Configuration Example.

Q. How does DHCP work with the WLC?

A. The WLC is designed to act as a DHCP relay agent to the external DHCP server and acts like a DHCP server to the client. This is the sequence of events that occurs:

1. Generally, WLAN is tied to an interface which is configured with a DHCP server.
2. When the WLC receives a DHCP request from the client on a WLAN, it relays the request to the DHCP server with its management IP address.
3. The WLC shows its Virtual IP address, which must be a non-routable address, usually configured as 1.1.1.1, as the DHCP server to the client.
4. The WLC forwards the DHCP reply from the DHCP server to the wireless client with its Virtual IP address.

Note: You can also configure the WLC to act as a DHCP server. For more information on how to configure a WLC as a DHCP server, refer to the Configuring DHCP Scopes section of the document Cisco Wireless LAN Controller Configuration Guide Release 5.1.

Q. What are all the authentication mechanisms supported by WLC?

A. WLC supports various layer 2 and layer 3 client authentication mechanisms. Layer 2 authentication mechanisms include WEP, WPA, WPA2, and 802.1x. Layer 3 authentications are commonly web authentication and web passthrough. For more information on how to configure the WLC for various authentication mechanisms, refer to the document Authentication on Wireless LAN Controllers Configuration Examples.

Q. How do I change power and channels for a LAP?

A. Once a LAP registers to a WLC, all the configuration for a LAP is done on the WLC. There is a built-in feature in WLC called RRM, wherein the WLC internally runs an algorithm and automatically adjusts the channel and power settings as per the deployment of LAPs. RRM is turned on by default on the WLC. You need not change the channel and power settings for a LAP, but you can override the RRM feature and statically assign power and channel settings for a LAP. For more information on how to manually configure the channel and power settings, refer to the Statically Assigning Channel and Transmit Power Settings to Access Point Radios section of the document Cisco Wireless LAN Controller Configuration Guide, Release 5.1.

Q. I have multiple WLCs in my network. Is there any device or software available to manage multiple WLCs in my network?

A. Yes, the Wireless Control System (WCS) is a server software that can manage multiple WLCs on the network. It manages the WLCs, their associated access points, and clients. For more information on the WCS, refer to Cisco Wireless Control System Configuration Guide, Release 5.0.

Q. How do I edit the WLC configuration file?

A. When you save the WLC configuration, the controller stores it in XML format in flash memory. In order to enable you to easily read and modify the configuration file, the controller software (release 5.2 or later) converts it to a CLI format.

When you upload the configuration file to a TFTP or FTP server, the controller initiates the conversion from XML to CLI. You can then read or edit the configuration file in the CLI format on the server. When you are finished, you download the file back to the controller, where it is converted to an XML format and saved.

For step-by-step instructions on how to edit the configuration file, refer to the Editing Configuration Files section of the WLC Configuration Guide 6.0.

Q. Can I push configurations from one WLC directly to other WLCs?

A. No. You cannot push configurations from one WLC directly to other WLCs. In order to transfer the file to other WLCs, you must upload the configuration file from a WLC to the TFTP server, and then download the file from the TFTP server to the desired WLC.

In order to upload and download a file from WLC to the TFTP server, refer to the Managing Controller Software and Configurations section of Cisco Wireless LAN Controller Configuration Guide, Release 5.0.

Note: Before you transfer the file from WLC to TFTP server, make sure that both the WLCs run the same software version.

Q. How do I find the version of code that runs on the WLC?

A. From the wireless LAN controller GUI, click **Monitor > Summary**. In the Summary page, the **Software Version** field shows the version of firmware that runs on the wireless LAN controller.

In order to find the version of firmware that runs on the WLC through the WLC CLI, use the command **show run-config**.

```
(Cisco Controller) >show run-config
```

```
Press Enter to continue...
```

```
System Inventory
Burned-in MAC Address..... 00:0B:85:33:52:80
```

```
Press Enter to continue Or <Ctl Z> to abort
```

```
System Information
Manufacturer's Name..... Cisco Systems Inc.
```

```

Product Name..... Cisco Controller
Product Version..... 4.0.217.0
RTOS Version..... 4.0.217.0
Bootloader Version..... 4.0.217.0
Build Type..... DATA + WPS
Compact Flash Size..... 256 MB

```

In order to view the active boot image, use the command **show boot**

```

(Cisco Controller) >show boot
Primary Boot Image..... 4.0.217.0 (active)
Backup Boot Image..... 4.0.155.5

```

Q. What happens to the wireless network when I perform a software upgrade? Do *all* the access points (APs) registered to a WLC go down until they are upgraded, or are they upgraded one at a time so that the wireless network can remain up (except for the specific APs that undergo the upgrade)?

A. Once the WLC is upgraded, it must be rebooted for the changes to take effect. Within this time, connectivity to the WLC is lost. LAPs registered to a WLC lose their association to the WLC, so service to the wireless clients is interrupted. When you upgrade the controller's software, the software on the controller's associated access points is also automatically upgraded.

When an access point loads software, each of its LEDs blinks in succession. Up to 10 access points can be concurrently upgraded from the controller. Do not power down the controller or any access point during this process; otherwise, you might corrupt the software image. Upgrading a controller with a large number of access points can take as long as 30 minutes, depending on the size of your network. However, with the increased number of concurrent access point upgrades supported in software release 4.0.206.0 and later, the upgrade time should be significantly reduced. The access points must remain powered, and the controller must not be reset during this time.

Q. What are the guidelines to follow before performing a wireless LAN controller upgrade?

A. Cisco recommends that the upgrade be performed over a LAN or other high-speed, low-latency link. A very slow network connection might cause TFTP to timeout, and the upgrade will not be successful.

Cisco recommends the controller be upgraded only from a tftp daemon on the same segment as the wireless LAN controller when you use TFTP as the transfer mode.

When you attempt to upgrade the controller using an associated wireless client as the TFTP or FTP server, the upgrade fails. The wireless LAN controller does not allow a (T)FTP transfer from a daemon that is located on a client associated to an AP joined to the WLC. (See CSCsi73129 for more information.)

In addition to these, follow the guidelines documented in the section Guidelines for Upgrading Controller Software of the configuration guide.

Q. Which controller functions require a reboot?

A. After you perform these functions on the controller, you must reboot the controller in order for the changes to take effect:

- ◆ Enable or disable link aggregation (LAG)
- ◆ Enable a feature that is dependent on certificates (such as https and web authentication)
- ◆ Add new or modify existing SNMP v3 users
- ◆ Install a license, change the license feature set, or change the priority of an AP-count evaluation license on a controller

Q. Can a Cisco IOS Software–based access point (AP) that has been converted to lightweight mode register with Cisco 4100 Series WLCs?

A. No, Cisco IOS Software–based APs that are converted to lightweight mode cannot register with the Cisco 40xx, 41xx, or 3500 WLCs. These lightweight APs (LAPs) can register only with the Cisco 4400 and the 2000 series WLCs. For information on the restrictions of APs that are converted to lightweight mode, refer to the *Restrictions* section of Upgrading Autonomous Cisco Aironet access points to Lightweight Mode.

Q. What is the maximum number of APs supported on the 4402 and 4404 wireless LAN controllers (WLCs)?

A. The limitation on the number of supported access points is based on the hardware that you have. The 4402 WLC with two gigabit Ethernet ports comes in configurations that support 12, 25, and 50 Light Weight Access Points (LAPs). The 4404 WLC with four gigabit Ethernet ports supports 100 LAPs.

Note: Mesh access points are also available in both indoor and outdoor deployments. For more information on number of access points (including mesh APs) supported on each controller model, refer to Table 8–3 *Mesh Access Points Supported by Controller Model* in the Controlling Mesh Access Point section of the Wireless Lan Controller Configuration Guide 6.0.

Q. How does roaming occur in a WLC environment?

A. Roaming is a process where the client can retain uninterrupted application sessions on its move. When a wireless client associates and authenticates to a WLC, it places an entry for that client in its client database. This entry includes the MAC and IP addresses of the client, security context and associations, quality of service (QoS) contexts, the WLAN, and the associated LAP. When a client roams to another LAP associated to the same WLC, it just updates the client database with the new LAP information so that the data can be forwarded appropriately to the client. When a client roams to a LAP associated with a different WLC, either in same or different subnets, it sends the information in the client database to the new WLC. This helps client to retain its IP address across roams and maintain uninterrupted TCP sessions. For more information on roaming in the WLC environment, refer to the Configuring Mobility Groups section of the *Cisco Wireless LAN Controller Configuration Guide, Release 5.1*.

Q. How are guest users handled by WLC?

A. Guest users are third-party network users, who needs limited access to the network resources and internet connectivity. WLC provides wireless and wired guest access using the existing wireless network infrastructure. Usually a separate SSID is provided for wireless guest users. Guest users on both the wired and wireless networks are assigned a separate VLANs, which provides isolation of guest traffic from the rest of the data traffic. This provides better control over the guest traffic and greater network security. Guest users are usually authenticated through Web authentication. For more information on guest access, refer to the document Wireless Guest Access FAQ.

In order to obtain guest user logs, enable Radius accounting for the users, and use this command: **debug aaa all enable**

Q. How do I configure a local database on the wireless LAN controller (WLC)? What are the special characters that can be used for the local net user username and passwords?

A. The local user database stores the credentials (username and password) of all the local network users. These credentials are then used to authenticate the users. You can configure local network users either through the GUI or the CLI. You can enter up to 24 alphanumeric characters. All the special characters can be used when you configure username and passwords through CLI, but the single quote character cannot be used when you configure username and password through GUI.

From the CLI, use these commands to create a local net user:.

- ◆ **config netuser add <username> <password> wlan <wlan_id> userType permanent description <description>** Adds a permanent user to the local user database on the WLC.
- ◆ **config netuser add <username> <password> {wlan | guestlan} {wlan_id | guest_lan_id} userType guest lifetime seconds description <description>** Adds a guest user on a WLAN or wired guest LAN to the local user database on the WLC.

From the GUI, you can configure local net users from the **Security > AAA > Local Net Users** page.

Q. Is it possible to automatically delete the local net user on the WLC?

A. Local Net users are not automatically deleted. You have to delete them manually. In order to delete the user, go to the **Security > AAA > Local Net Users** page. In order to remove a user, place the mouse over the icon  and click **Remove**. If a local net user is configured as a guest user, you must specify the life time, after which the user is automatically deleted. The configurable range is between 60 seconds and 2592000 seconds.

Q. What is a Mobility Group?

A. Mobility group is a group of WLCs configured with the same Mobility group name. The client can roam seamlessly between the WLCs in the same mobility group. WLCs in a mobility group provide for redundancy among themselves. For more information on Mobility Groups, refer to the document Wireless LAN Controller (WLC) Mobility Groups FAQ.

Q. How many WLCs can I have in the same mobility group?

A. You can place up to 24 regular WLCs (Cisco 2000, 4100, and 4400 series) in a single mobility group. You can configure up to 12 Wireless Services Module (WiSM) blades in one mobility group. Therefore, up to a maximum of 3600 access points (APs) are supported in a single mobility group.

Note: With WLC release 5.1, there can be up to 72 WLCs in a Mobility domain.

Q. Does the Cisco 4400 Series WLC support Internetwork Packet Exchange (IPX) protocol? Does any Airespace product support IPX protocol?

A. No, IPX protocol is not supported on any platforms of the Cisco WLC.

Q. What are the prerequisites to access the graphical user interface (GUI) of the wireless LAN controller (WLC)?

A. The wireless LAN controller GUI is fully compatible with Microsoft Internet Explorer version 6.0 SP1 (or later) and Mozilla Firefox 2.0.0.11 (or later).

Note: Opera and Netscape are not supported.

Note: Internet Explorer 6.0 SP1 (or later) and Mozilla Firefox 2.0.0.11 (or later) are the only browsers supported for accessing the controller GUI and for using web authentication.

Q. How do I retrieve Cisco wireless LAN controller (WLC) MIBs on the web?

A. You can download the Cisco WLC MIBs from the Wireless Downloads (registered customers only) page.

Complete these steps in order to download the WLC MIBs:

1. From the Wireless Downloads page, click **Wireless LAN Controller**, and choose the WLC platform for which you need the MIBs.
2. The Software Download page for the WLC appears. This page contains all the files for the WLC including the MIBs.
3. Choose a software version and download the standard MIBs and the Cisco specific MIBs. These two files should be downloaded and contain the MIBs. The filenames look similar to this example:

`Standard-MIBS-Cisco-WLC4400-2000-XXXXXX.zip`

`Cisco-WLC-MIBS-XXXX.zip`

Q. In guest tunneling, how many Ethernet over IP (EoIP) tunnels can be formed between a single anchor WLC to different internal WLCs?

A. A single anchor WLC supports up to 71 EoIP tunnels with one tunnel per internal WLC. These WLCs can be of different mobility groups.

Q. What are the functional differences between the 2100 Series WLCs and the 4400 WLCs?

A. The major differences between the 2100 and 4400 Series WLCs are in the features they support.

This Hardware features is not supported on 2100 series WLCs

- ◆ Service Port (separate out-of-band management 10/100-Mbps Ethernet interface)

These software features are not supported on 2100 Series WLCs:

- ◆ VPN termination (such as IPSec and L2TP)
- ◆ VPN passthrough option
- ◆ Termination of guest controller tunnels (origination of guest controller tunnels is supported)
- ◆ External web authentication web server list
- ◆ Layer 2 LWAPP
- ◆ Spanning tree protocol
- ◆ Port mirroring
- ◆ AppleTalk
- ◆ QoS per-user bandwidth contracts
- ◆ IPv6 pass-through
- ◆ Link aggregation (LAG)
- ◆ Multicast-unicast mode

A 4400 Series WLC supports all the forementioned hardware and software features.

Q. Which lightweight access points (LAPs) do the 4100 Series WLCs support?

A. Only the Airespace 1200, 1250, the Cisco 1000 Series, and the Cisco 1500 Series LAPs work with the 4100 Series WLCs.

Q. Can I use this ASA /PIX as a DHCP server instead of windows DHCP server in order to assign IP addresses to my Wireless Clients?

A. Yes, you can use ASA/PIX as a DHCP server for wireless clients. Ensure that interface of the WLAN to which the client belongs, is on the same subnet as the ASA/PIX interface on which the server is enabled. However you can't assign default gateway to the clients. PIX/ASA declares itself as the default gateway to the clients. For more information on how to configure ASA as a DHCP server PIX/ASA as a DHCP Server and Client Configuration Example.

Q. Is it possible to go back and make corrections in the wireless LAN controller (WLC) configuration wizard at the time of the initial configuration?

A. Yes, this can be done with the – (hyphen) key. Use this key to re-enter the previous parameter value.

For example, you use the WLC configuration wizard in order to configure the WLC from scratch.

Instead of entering the username as **admin**, you enter it as **adminn**. In order to correct this, enter – (hyphen key) at the next prompt, then click **Enter**. The system returns to the previous parameter.

```
(Cisco Controller)

Welcome to the Cisco Wizard Configuration Tool
Use the '-' character to backup
System Name [Cisco_e8:38:c0]: adminn
Enter Administrative User Name (24 characters max): -

System Name [Cisco_e8:38:c0] (31 characters max):
```

Q. In accordance to RFC 1907 for Simple Network Management Protocol (SNMP), the SNMP location field should support a size from 1–255. However, I am unable to enter more than 31 characters in the SNMP location field. Why?

A. This is due to Cisco bug ID CSCsh58468 (registered customers only) . An user can enter only 31 characters. Currently there is no workaround for this.

Q. With the Management via Wireless feature enabled on wireless LAN controllers (WLCs) in a mobility group, I can only access one WLC from that mobility group, but not all. Why?

A. This is an expected behavior. When enabled, the Management via Wireless feature allows a wireless client to reach or manage only the WLC to which its associated access point is registered. The client cannot manage other WLCs, even though these WLCs are in same mobility groups. This is implemented for security, and recently was tightened down to just the one WLC in order to limit exposure.

The Cisco WLAN Solution Management over Wireless feature allows Cisco WLAN Solution operators to monitor and configure local WLCs using a wireless client. This feature is supported for all management tasks, except uploads to and downloads from (transfers to and from) the WLC.

This can be enabled through the WLC CLI with the **config network mgmt–via–wireless enable** command.

On the GUI, click **Management**; from the left–hand side click **Mgmt Via Wireless**, and check the box **Enable Controller Management to be accessible from Wireless Clients**.

Note: When you enable this option, you can expose the data. Ensure that you have enabled a proper authentication and encryption scheme.

Q. Is it possible to assign an integrated controller in a 3750 Switch and a 4400 wireless LAN controller within the same mobility group?

A. Yes, it is possible to create a mobility group between a Catalyst 3750 Switch with an integrated controller and a 4400 WLC.

Q. Are there any basic requirements to maintain when I use the mobility anchor feature in order to configure wireless LAN controllers (WLCs) for guest access?

A. These are the 2 basic requirements that need to be maintained when you use mobility anchor in order to configure WLCs for guest access.

- ◆ The mobility anchor of the local WLC must point to the anchor WLC, and the mobility anchor of the anchor WLC must point only to itself.

Note: You can configure redundant anchor WLCs. Local WLC uses them in the order WLCs are configured.

- ◆ Make sure you configure the same security policy for the service set identifier (SSID) on both the local and anchor WLCs. For example, if the SSID is "guest" and you turn on web authentication on the local WLC, make sure the same SSID and security policy is also configured on the anchor WLC.
- ◆ For the mobility anchor feature to work well, make sure that the anchor WLC and the local WLC use the same IOS version.

Q. What are some of the options that can be configured on a Cisco wireless LAN controller (WLC) to improve its interoperability with non-Cisco devices?

A. The interoperability of a WLC can be improved through these options:

- ◆ Proprietary features reduce the chance of interoperability between third party devices. These are the proprietary features of Cisco:
 - ◇ Aironet IE – Aironet IE contains information, such as the access point name, load, number of associated clients, and so on sent out by the access point in the beacon and probe responses of the WLAN. CCX clients use this information to choose the best access point with which to associate.
 - ◇ MFP: Management Frame Protection is a feature introduced to protect the management frames, such as de-authentication, disassociation, beacons, and probes wherein the access point adds a Message Integrity Check Information Element (MIC IE) to each of the management frames. Any discrepancy in the MIC IE generates an alert.

These features are enabled by default for any WLAN that is created on the WLC. In order to disable these features, click the WLANs menu in the WLC. A list of WLANs configured on the WLC displays. Click the WLAN to which the client wants to associate. Under the Advanced Tab of WLANs > Edit page, uncheck the boxes that correspond to Aironet IE and MFP.

- ◆ Short Preamble A short preamble improves the throughput performance and is enabled by default. Certain devices, such as SpectraLink Phones can work only with long preambles. In such cases, it helps in association to uncheck short preambles. In order to disable the short preamble, click the **Wireless** menu of the WLC GUI. Then click the **802.11b/g** > network menu on the left-hand side. Uncheck the **Short Preamble** box.
- ◆ Enable the broadcast service set identifier (SSID) on the WLAN With the broadcast SSID enabled, the WLAN/SSID information is sent in the beacons. This also help the clients that perform passive scans (those that do not transmit probe request), as well as clients configured without an SSID to associate with the WLC through this

WLAN.

Note: Make sure that you have strong authentication mechanisms in place since unintended clients can associate to your wireless network.

- ◆ Disable aggressive load balancing globally on the WLC.

Q. Can a wireless LAN controller (WLC) be managed by CiscoWorks (which is used to manage routers and switches)?

A. Yes. 4400 series WLC models (such as 4402 and 4404) can be managed by CiscoWorks.

Q. What is a Rogue AP? Can the rogue APs in my wireless network be automatically blocked?

A. APs that are not part of your wireless deployment are called rogue APs. It can be either an autonomous AP or Lightweight AP that happens to be in the range of authorized APs. Rogue APs cannot be automatically blocked. This must be done manually. The reason for this is that, when a rogue AP is found, the finding AP disassociates the clients of the rogue AP, which causes denial of service to the clients. This can cause legal issues if the AP of the neighbor is detected as a rogue, and its clients are denied service. For more information on how rogue APs are detected by the WLC, refer to the document Rogue Detection under Unified Wireless Networks.

Q. What is the maximum number of rogue access points (APs) supported per WLC?

A. The 4400 Series wireless LAN controller supports up to 625 rogues, which includes acknowledged rogues, while the 2100 Series supports 125 rogues.

Q. Can the wireless LAN controller (WLC) send email notifications to the administrator when a critical event occurs?

A. The WLC does not send email, but it can send traps to the Network Management System (NMS) stations, such as HP OpenView (HPOV). HPOV can perform things such as running scripts to send email on receipt of particular traps.

HPOV is a Hewlett Packard product range that consists of an extensive portfolio of network and systems management products. HPOV is most commonly described as a suite of software applications which allow large-scale system and network management of an organization's IT assets. HPOV includes hundreds of optional modules from HP as well as thousands of third parties which connect within the well-defined framework and communicate with one another.

Q. If the WLCs in the same mobility group are separated by Network Address Translation (NAT) boundaries, can they communicate mobility messages with each other?

A. In controller software releases earlier than 4.2, mobility between controllers in the same Mobility Group does not work if one of the controllers is behind a network address translation (NAT) device. This behavior creates a problem for the guest anchor feature where one controller is expected to be outside the firewall.

Mobility message payloads carry IP address information about the source controller. This IP address is validated with the source IP address of the IP header. This behavior poses a problem when a NAT device is introduced in the network because it changes the source IP address in the IP header. Hence, in the guest WLAN feature, any mobility packet that is routed through a NAT device is dropped because of the IP address mismatch.

In controller software release 4.2 and later, the Mobility Group lookup is changed to use the MAC address of the source controller. Because the source IP address is changed due to the mapping in the NAT device, the Mobility Group database is searched before a reply is sent to get the IP address of the controller that makes the request. This is done with the MAC address of the controller that makes the request.

Refer to Using Mobility Groups with NAT Devices for more information.

Q. The physical ports on the WLC are currently set to operate at 1000 mbps speed. Is it possible to change this port speed to 100 mbps?

A. No, the port speed on the WLC cannot be changed. These are set at 1000 mbps, full duplex speed only.

Q. I have set the Radio Resource Management (RRM) to the default settings on my WLC. However, I cannot find my RRM to automatically adjust the channel and power levels. Why?

A. RRM possibly does not work for any of these reasons

- ◆ The RRM works only if an AP hears RF signals from at least 3 nearby APs, with a third neighbor that transmits a signal strength greater than -65dbm. If any of these condition fails, the RRM does not work.
- ◆ The auto RRM feature includes channel adjustment, power adjustment, and coverage hole detection. These features do not work if they are either disabled or the method of assignment is chosen as manual.

While a fresh AP boots up, it initially keeps power at the default value of 1 (highest). When it sees 3 or more APs with power levels greater than -65 dBm (in the same RF-Mobility-Domain and same channel), it attempts RRM first (change channels). If not successful because the channels are manually fixed or there are more APs than channels available, the AP drops its power level.

Refer to Radio Resource Management: Concepts for more information on how RRM works.

Q. Does the wireless LAN controller (WLC) locally support EAP-PEAP authentication?

A. Through version 4.1, PEAP is not supported locally on the WLC. You need an external RADIUS server. With WLC version 4.2 and later versions, local EAP now supports PEAPv0/MSCHAPv2 and PEAPv1/GTC authentication.

Q. Can we place the lightweight access point (LAP) under Network Address Translation (NAT)? Does the Lightweight Access Point Protocol (LWAPP) from access point (AP) to WLC work through NAT boundaries?

A. Yes, you can place the LAP under NAT. On the AP side, you can have any type of NAT configured, but, on the WLC side, you can have only 1:1 (Static NAT) configured. PAT cannot be configured on the WLC side because LAPs cannot respond to WLCs if the ports are translated to ports other than 12222 or 12223, which are meant for data and control messages.

Q. How do I configure WLC to allow only 802.11g clients?

A. Use the **config 802.11b disable** command in order to disable or enable 802.11b/g transmissions for the whole network or for an individual Cisco radio

Note: You must use this command to disable the network before you use other config 802.11b commands. This command can be used any time the CLI interface is active.

Here is the syntax.

```
config 802.11b disable {network | Cisco_AP}
```

Here is an example on how to disable AP01 802.11b/g transmissions:

```
config 802.11b disable network
```

In order to disable **AP01** 802.11b/g transmissions, use this command:

```
config 802.11b disable AP01
```

Alternatively, you can use this command in order to disable the 802.11b data rates:

```
config 802.11b rate {disabled | mandatory | supported} rate
```

Q. What is the procedure to upgrade the operating system (OS) software on a Cisco WLC?

A. Refer to the document Wireless LAN Controller (WLC) Software Upgrade to provide the procedure for a software upgrade on your WLC.

Q. Can I upgrade the WLC from one major version to another directly?

A. You can upgrade or downgrade the WLC software only between two releases. In order to upgrade or downgrade beyond two releases, you must first install an intermediate release. For example, if your WLC runs a 4.2 or 5.0 release, you can upgrade your WLC directly to Software Release 5.1.151.0. If your WLC runs a 3.2, 4.0, or 4.1 release, you must upgrade your WLC to an intermediate release prior to the upgrade to 5.1.151.0. In order to know the upgrade path for any WLC version, refer to the Release Notes of the corresponding release.

Q. What is Beamforming?

A. Beamforming (also called ClientLink) is a spatial-filtering mechanism used at a transmitter to improve the received signal power or signal-to-noise (SNR) ratio at an intended receiver (client). Beamforming uses multiple transmit antennas to focus transmissions in the direction of an 802.11a or 802.11g client, which increases the downlink SNR and the data rate to the client, reduces coverage holes, and enhances overall system performance. Beamforming is supported on Cisco Aironet 1140 and 1250 series access points and works with all existing 802.11a and 802.11g clients. It is disabled by default.

For information on configuring Beamforming, refer to the Configuring Beamforming section of the Wireless LAN Controller Configuration Guide.

Q. Can I download a login banner for the wireless LAN Controller?

A. You can download a login banner file using either the controller GUI or CLI. The login banner is the text that appears on the screen before user authentication when you access the controller GUI or CLI using Telnet, SSH, or a console port connection.

Troubleshoot FAQ

Q. We have finished our initial deployment of lightweight access points (LAPs). When our clients move from one end of the building to the other, they stay associated with the AP to which they were closest. The clients do not appear to be handed off to the next-closest AP until the signal strength from the initial AP is completely depleted. why?

A. Coverage area of an AP is entirely controlled by the WLC. The WLC talks between its APs and manages their signal strength on the basis of how each AP senses other APs. However the client movement from one AP to other is entirely controlled by the client. The radio within the client determines when the client wants to move from one AP to the other. No setting on the WLC, AP, or the rest of your network can influence client's decision to roam to a different AP.

Q. I connected my WLC to Cat6500 switches configured for routing, and I configured HSRP between these switches. However, I am now unable to reach other subnets through WLC. How do I resolve this issue?

A. When HSRP is in place, a virtual IP address and MAC address is usually configured for the HSRP group, which is used for routing. Hosts continue to forward IP packets to this consistent IP and MAC address even when one of the switches go down and change over to a standby device takes place. Complete these steps in order to resolve the routing issue:

1. Make sure the virtual IP address is configured as the default gateway on the WLC.

Note: Certain earlier versions of WLC do not forward packets to HSRP MAC address, which results in failure to route packets. Upgrade the WLC in order to resolve this issue.

2. Make sure the virtual interface on the WLC is properly configured. For more information on interfaces, refer to the Configuring Ports and Interfaces section of the WLC Configuration Guide.

Q. How do I prevent loops on the WLC?

A. You can enable STP on the WLC to prevent loops . On the WLC GUI click **Controller**, and then navigate to the **Advanced** submenu located on the left side of the application. Click the **Spanning Tree** option, and choose **Enable** for **Spanning Tree Algorithm** located on the right side of the application.

By default, STP need not be enabled to prevent loops. Because each interface that is mapped to a WLAN on the WLC is mapped to primary and backup ports. Only one port is used at a

particular point of time. Traffic from the WLAN is forwarded only through the primary port. WLC never uses the secondary port when the primary port is active. WLC uses the secondary port only when the primary port is down, so loops will not occur by default.

Q. Is there any option to provide additional security to the network?

A. You can use option 82 in order to provide additional security. Option 82 blocks IP addresses to unauthorized clients that access the network. For more information, refer to the Configuring DHCP Option 82 section of the Cisco Wireless LAN Controller Configuration Guide, Release 6.0.

Q. Is there any way to recover my password for WLC?

A. If you forget your password in WLC version 5.1 and later, you can use the CLI from the controller's serial console in order to configure a new user name and password. Complete these steps in order to configure a new user name and password.

1. After the controller boots up, enter **Restore–Password** at the user prompt.

Note: For security reasons, the text that you enter does not appear on the controller console.

2. At the Enter User Name prompt, enter a new user name.
3. At the Enter Password prompt, enter a new password.
4. At the Re–enter Password prompt, re–enter the new password.

The controller validates and stores your entries in the database.

5. When the User prompt reappears, enter your new username.
6. When the Password prompt appears, enter your new password.

The controller logs you in with your new username and password.

Note: For WLCs that run earlier versions of firmware (prior to 5.1), there is no way to recover the password. If you use the Cisco Wireless Control System (WCS) in order to manage the WLC, wireless LAN controller Module (WLCM) or Wireless Services Module (WiSM), you should be able to access the WLC from the WCS and create a new administrative user without logging into the WLC itself. Or, if you did not save the configuration on the WLC after you deleted the user, then a reboot (power cycling) of the WLC should bring it back up with the deleted user still in the system. If you do not have the default admin account or another user account with which you can log in, your only option is to default the WLC to factory settings and reconfigure it from scratch.

Q. I changed the lightweight access point (LAP) mode of my 1030 access point (AP) from Local to Bridge mode and the 2006 WLC no longer detects it. How can I restore the 1030 AP back to its Local AP mode?

A. In order to configure the bridge in Local Mode, complete these steps:

1. Go to the WLC GUI and choose **Wireless >**. **It displays the list of APs that are currently registered to the WLC. Click on the AP for which you need to change the mode .**

Note: Check if the AP supports REAP mode. This must be **YES** for indoor bridging APs.

2. Check the option AP mode. If it says Bridge, then change it back to **Local**. This changes the Bridge AP to Normal AP.

For more information on how to configure the bridging mode, refer to Ethernet Bridging in Point-Point Wireless Mesh Network Configuration Example.

Q. I have set up a guest Wireless LAN and the WLC is physically separated from my internal LAN. I decided to use the internal DHCP feature of this WLC but my wireless clients do not get IP addresses from the WLC. How do the wireless guest users get IP addresses from the WLC when they are connected on a physically separate network?

- ◆ Check if the DHCP scope is enabled on the WLC. In order to check this, click the **Controller** Menu and click **Internal DHCP server** from the left-hand side.
- ◆ Generally, the DHCP server is specified on the interface, which maps to the WLAN. Make sure that the management interface address of the WLC is specified as the DHCP server on the interface that maps to the guest user WLAN. Alternatively, you can enable the DHCP Server override option on the **WLANs > Edit** page and specify the management interface address of the WLC in the **DHCP server IP Addr** field..

Q. I have a 4400 Series wireless LAN controller (WLC) and lightweight access points (LAPs) registered to the WLC. I have configured WLANs for the clients to connect on the WLC. The problem is that the WLC does not broadcast the service set identifiers (SSIDs) that I configured for the WLANs. Why?

A. The Admin Status and the Broadcast SSID parameters are disabled by default. Complete these steps in order to enable Admin Status and Broadcast SSID:

1. Go to the WLC GUI and choose **Controller > WLANs**. The WLANs page appears. This page lists the WLANs that are configured.
2. Select the WLAN for which you want to enable broadcasting of the SSID and click **Edit**.
3. In the WLAN > Edit page, check **Admin Status** in order to enable the WLAN. Also, check **Broadcast SSID** in order to ensure that the SSID is broadcast in the beacon messages sent by the AP.

Q. Does the Cisco Unified Wireless solution support redundant WLCs in the DMZ for guest tunneling?

A. Yes, WLCs in the DMZ support redundant WLCs in the DMZ for guest tunneling. For more information on how to configure redundant WLCs, refer to the Configuring Auto-Anchor Mobility section of the document Cisco Wireless LAN Controller Configuration Guide, Release 5.1.

Q. Wireless LAN Clients associated with the lightweight access points are not able to get IP addresses from the DHCP server. How do I proceed?

A. The DHCP server for a client is usually marked on the interface, which maps to the WLAN to which the client. Check if the interface is configured appropriately. For more

information on how to troubleshoot DHCP related issues, refer to the IP Address Issues section of the document Troubleshooting Client Issues in the Cisco Unified Wireless Network.

Q. Are there any documents that explain troubleshooting client connectivity issues in a Cisco Unified wireless network?

A. For detailed information on troubleshooting client issues, refer to these documents.

- ◆ Unified Wireless Network: Troubleshoot Client Issues
- ◆ Understanding Debug Client on Wireless LAN Controllers (WLCs)

Q. My 1131 lightweight access point (LAP) does not register with my 4402 wireless LAN controller (WLC). What can be the possible reason for this?

A. One common reason is that the Lightweight Access Point Protocol (LWAPP) Transport Mode is configured on the WLC. A 4402 WLC can operate in both Layer 2 and Layer 3 LWAPP mode. Whereas, an 1131 LAP can only operate in Layer 3 mode. Layer 2 mode is not supported on the 1131 LAP. So, if the WLC is configured with the LWAPP Transport Mode of Layer 2, then your LAP does not join the WLC. In order to overcome this problem, change the LWAPP Transport Mode of the WLC from Layer 2 to Layer 3.

In order to change the LWAPP Transport Mode using the GUI, go to the WLC page and locate the second selection in the main field which is LWAPP Transport Mode. Change this to Layer 3 and reboot the WLC. Now, your LAP is able to register with the WLC. For more information on issues related to LAP registration, refer to the document Troubleshoot a Lightweight Access Point Not Joining a Wireless LAN Controller.

Q. No traps are generated by the WLC for Ad-Hoc rogues and the SNMP debugs on the WLC do not show any traps from the WLC for Ad-Hoc even though the WLC GUI reported the Ad-Hoc rogues. The WLC runs firmware version 3.2.116.21. Why does this happen?

A. This is due to Cisco bug ID CSCse14889 (registered customers only) . The WLC consistently sends traps for detected rogue access points (APs) but not for detected Ad-Hoc rogues. This bug is fixed in WLC firmware versions 3.2.171.5 and later.

Q. We have an enterprise Cisco Airespace WLAN infrastructure. WLAN clients are unable to browse a Microsoft Active Directory (AD) domain. This issue is seen within one of our buildings. Other buildings do not have the problem. We do not use any access control list (ACL) internally. Also, when a failed client is hard-wired, they can immediately browse the Microsoft AD domain. What could be the problem?

A. One of the reasons can be that multicast mode is disabled on the WLC. Enable multicast mode on the WLC and check if you are able to access the Microsoft AD domain.

Q. Does Layer 3 mobility work with an access point (AP) Group VLAN configuration?

A. Yes, Layer 3 mobility works with an AP Group VLAN configuration. Currently, traffic sources from a Layer 3 roamed wireless client is put on the dynamic interface assigned on the WLAN or the interface of the AP Group VLAN..

Q. Why are our access points (APs) that are registered to other WLCs that are in the same RF group shown as rogues?

A. This can be due to Cisco bug ID CSCse87066 (registered customers only) . LWAPP APs in the same RF group are seen as rogue APs by another WLC for one of these reasons:

- ◆ The AP sees more than 24 neighbors. The neighbor list size is 24, so the 25th AP is reported as a rogue.
- ◆ AP1 can hear the client that communicates to AP2, but AP2 cannot be heard. Therefore, it cannot be validated as a neighbor.

The workaround is to manually set the APs to known internal on the WLC and/or WCS. Complete these steps on the WLC in order to manually set the APs to known internal:

1. Go to the WLC GUI and choose **Wireless**.
2. Click **Rogue Aps** in the left side menu.
3. From the Rogue-AP list, choose the specific access point and click **Edit**.
4. From the Update Status menu, choose **Known internal**.
5. Click **Apply**. This bug is fixed in version 4.0.179.11.

Q. I have a 1200 Lightweight Access Point (LAP) to be registered with my wireless LAN controller (WLC). I have configured my DHCP server with option 43. How can I verify whether DHCP option 43 is functioning properly?

A. With DHCP option 43, the DHCP server provides the IP address of the WLCs along with the IP address provided through DHCP. This can be verified from the LAP if the AP is a Cisco IOS based Lightweight Access Point Protocol (LWAPP) AP, such as the 1242 or 1131AG LAP. In these cases, issue the **debug dhcp detail** command on the AP side in order to see if the AP successfully receives the option 43 information and what it receives.

Q. My 2006 WLC shows that different channels have been assigned to the registered access points (APs). However, when I scan with Aironet Desktop Utility (ADU) or Netstumbler, all the APs are in the same channel (1). What is the reason?

A. This problem occurs when these registered APs are in close proximity with each other. You might be hitting Cisco bug ID CSCsg03420 (registered customers only) .

Q. When I issue the ipconfig/all command at the command prompt of my PC, a different DHCP server address shows. It shows 1.1.1.1 as the DHCP server IP address. This is the virtual interface IP address of the WLC and not the DHCP server address. Why is this shown as the DHCP

server?

A. This is because the 1.1.1.1 virtual interface address acts as a DHCP proxy for the original DHCP server. If you want to see the original DHCP server address at the output of the **ipconfig/all** command, then disable the DHCP proxy feature in the WLC to which the client is associated. This can be disabled with the **config dhcp proxy disable** command.

This command will replace the 1.1.1.1 virtual interface address, which shows up itself as the DHCP server, with the actual DHCP server IP address that you defined on the interface or in the override option of the WLAN.

Q. We have a couple of Access Control Servers (ACS) that authenticate the wireless clients associated to wireless LAN controllers (WLCs). One ACS acts as a primary authenticating server and the other as a failover server. If the primary server fails, the WLC falls back to secondary for authenticating the wireless clients. Once the primary server comes back up, the WLC does not fallback to the primary server. Why?

A. This is an expected behavior. These steps occur when a client is authenticated through the WLC in multiple ACS deployments:

1. Upon boot up, the WLC determines the active ACS.
2. When this active ACS does not respond to the RADIUS request from the WLC, the WLC searches and makes a failover to the secondary ACS.
3. Even when the primary ACS comes back up, the WLC does not fall back to it until the ACS to which the WLC is currently authenticating fails.

In such cases, reboot the WLC in order for the WLC to identify the primary ACS again and fallback to it. This fallback does not occur immediately after reboot. It might take some time.

Q. I am not able to Secure Shell (SSH) into the wireless LAN controller (WLC) when I use SecureCRT SSH v2 SH client software. My WLC runs version 4.0.179.8.

A. SecureCRT works only with WLCs that run version 4.0.206.0 or later. Upgrade your WLC to this version. Then, you can use SecureCRT SH client in order to SSH into the WLC.

Q. How do I encrypt the configuration files on the WLC?

A. Encryption of configuration files is already available in WLCs. If you choose from the WLC GUI, **Commands > Upload File**, you see the **Configuration File Encryption** checkbox.

You can force the file to be encrypted through WCS in this way.

- ◆ From the WCS GUI, choose **Configure controller**. It displays the list of WLCs configured in the WCS. Click on a WLC.
- ◆ In the left-hand side, click the **commands** option. You receive a list of controller commands.
- ◆ Under **Upload/Download Commands**, choose **download config** from the drop-down menu. At this time, you see this message: **Note: Configuration file encryption key is not set. Downloading configuration file will fail if encryption**

key is needed. Please click here to setup encryption.

Basically, you can force the WCS to always set an encryption key for WLC configurations. Encryption is not enabled by default, but it can be enabled both in WLC and WCS, as needed.

Q. How do WLCs support oversized access points?

A. Controller software release 5.0 or later allows you to upgrade to an oversized access point image by automatically deleting the recovery image to create sufficient space. This feature affects only access points with 8 MB of flash (the 1100, 1200, and 1310 series access points). All newer access points have a larger flash size than 8 MB. As of August 2007, there are no oversized access point images, but as new features are added, the access point image size will continue to grow. For more information, refer to the Supporting Oversized Access Point Images section of the Cisco Wireless LAN Controller Configuration Guide, Release 6.0.
